## CONSENT DECREE, DOJ No. 90-5-1-1-09767

## City-Wide Hydraulic Model Update

## Due May 10, 2019

Enclosed is the City of Tyler City-Wide Hydraulic Model Update report that follows the requirements listed in Section V. COMPLIANCE REQUIREMENTS, Sub-part B. Hydraulic Model Update of *United States et. al v. City of Tyler* Consent Decree.

**CERTIFICATION:**

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering such information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including possibility of fine and imprisonment for knowing violations.

# 1.0 Executive Summary

Pipeline Analysis, LLC in association with LNV, Inc. have developed an all-pipes hydraulic model of the City of Tyler sanitary sewer system. Sewer lines ten (10) inch and larger (and smaller critical sewers) were modeled using field obtained survey data. The non-critical sewer lines, sizes smaller than 10 inch, were also included in the model using available data and TCEQ minimum slopes. This hydraulic model will be used to evaluate the hydraulic capacity of the existing collection system under current and future conditions, including dry and wet weather.

The hydraulic model selected was the Bentley SewerGEMS™. This model is widely used by municipalities and engineers across the country to analyze wastewater collection systems. By developing a comprehensive hydraulic model of the wastewater collection system, the City of Tyler has an important tool in optimizing the collection system hydraulic performance and addressing current and future system capacity.

Specific projects will be developed to remediate confirmed capacity constraints following detailed field verification. Hydraulic improvements in association with on-going system condition assessments and rehabilitation programs will extend the life of the collection system assets to provide reliable service to residents.

This report describes the methodology used to construct and calibrate the hydraulic model in compliance with *Section V. Compliance Requirements Sub-part B. Updating Hydraulic Model* of the Consent Decree. Within this report, several model building parameters are covered such as the modeling software, creation of the model network from GIS shape files, field elevation surveying, drainage area distribution, rainfall influence distribution, model calibration for dry and wet weather conditions, and development of the design rainfall event.

# 2.0 Introduction

## 2.1 Background

The City of Tyler has developed a hydraulic wastewater model to analyze the City's Wastewater Collection and Transmission System (WCTS). The hydraulic model consists of two (2) separate wastewater service areas namely; Westside and Southside wastewater treatment service areas. The development of a hydraulic model will ensure consistent assessment of future growth and system capacity requirements for current and future conditions. The approach to the hydraulic modeling of the WCTS is organized around the City's objectives for this project:

- Reduction in Sanitary Sewer Overflows (SSOs)
- Collection system capacity assurance
- Cost controls and least cost alternatives
- Attainment of long-term Infiltration/Inflow (I/I) solutions
- Compliance with EPA Consent Decree hydraulic modeling and capacity assessment requirements and timelines

## 2.2 Purpose

The purpose of this project is to provide the technical assistance necessary to assist the City of Tyler in the development and execution of a hydraulic model to address Potential Capacity Constraints (PCCs) in the City's WCTS. A hydraulic wastewater system model will equip the City with a tool for analyzing system conveyance capacities, restricted flow, future growth and potential overflow locations. The City will use this model to assess and predict potential capacity requirements and develop least cost strategies to optimize system performance.

# 3.0 Wastewater Flow and Rainfall Monitoring

Wastewater flow data was obtained from fourteen (14) temporary flow meters in the Westside service area and six (6) temporary flow meters from the Southside service area in order to establish flow hydraulics at key locations within the collection system service areas for both dry and wet weather scenarios. Rainfall totals from eight (8) rainfall gauges were used for wastewater flow evaluation.

The location of each flow meter established the physical limits of the flow meter basin and the corresponding wastewater pipes and manholes within the meter basin. These are defined as all lines and manholes upstream of the flow. Figure 1 presents a schematic diagram showing the relationship between each flow meter. Table 1 presents the meter locations and pipe sizes monitored.

The flow metering for the two service areas was initially undertaken during the period April through June 2015 which are typically wet weather months. Additional metering was conducted specifically for meter sites 002, 003 and 018 from December 2016 through March 2017 to obtain supplemental data at these locations. The primary goal of the flow metering data analysis was to characterize the dry weather flow condition and the wet weather response of the collection system for the purposes of calibrating the hydraulic model. A secondary goal was the characterization of wet weather issues within the collection system.

# 4.0 Hydraulic Model Development

A key element to a successful wastewater collection system plan is to develop a collection system model that accurately simulates the conveyance of wastewater flows. The City of Tyler WCTS model includes system elements such as gravity lines, manholes, lift stations, and force mains. The purpose of this section is to summarize the existing sanitary system, GIS data review, primary modeling tools and software, data used to model the wastewater system, model limitations and assumptions.

The primary source of data was GIS data provided by the City's GIS department and included shapefiles for the sanitary system, information for lots and streets, as well as existing and future land use information. This database formed the basis of all the modeling work. The GIS data included field surveyed and inspected data conducted by Pipeline Analysis LLC for manholes and sewer lines ten (10) inch and larger, including small critical sewers. A lift station condition assessment and drawdown testing were also conducted by Pipeline Analysis LLC to determine capacity of each pump and that of multiple pumps operating together.

## 4.1 Primary Modeling Tools

SewerGEMS, developed by Bentley Software, was used for analysis of the City's wastewater collection system. SewerGEMS software was chosen for its capabilities of analyzing systems that have complicated pumping and pressure sewers with multiple lift stations and its built-in hydraulic and hydrology tools. Rainfall dependent inflow and infiltration (RDII) is computed using defined contributing areas and inflow parameters for volume and rate as determined through model calibration compared to observed rainfall and field collected flow data. One of SewerGEMS built-in functions is its capability to calculate RDII flows through the RTK values of a particular contributing area with its corresponding storm event data. This RTK method uses three triangular unit hydrographs to represent the various ways that precipitation contributes to RDII. The R, T and K parameters are defined as follows:

- R parameter represents the fraction of the total rainfall volume that enters the sewer system as RDII. The sum of three unit hydrographs (R1, R2, and R3) allocates total R value for the storm event.
- T parameter represents the time from the onset of rainfall to the peak flow in hours
- K parameter represents the declining portion of the triangular unit hydrograph. K represents the ratio of time to recession.

SewerGEMS can be configured to represent a wide range of system inflow and infiltration types and has been proven through extensive use worldwide. SewerGEMS software's stability allows for the modeling of very complex flow conditions, including nearly all wastewater systems, from simple gravity systems to complex systems with multiple pumping stations. SewerGEMS uses a Bentley enhanced SWMM 5 numerical solver to allocate RDII flows developed from RTK values.

While SewerGEMS can attribute RDII flows after proper R, T, K values have been assigned, it does not have a software function to assist the modeler in finding the R, T, K values. Sanitary Sewer Overflow Analysis and Planning toolbox (SSOAP) is a computer software developed by the EPA designed to quantify the RDII values seen in a sanitary sewer system. SSOAP is designed to interface with a SWMM 5 numerical solver. By inputting contributing areas and flow metering data into SSOAP, corresponding RTK values were identified by SSOAP.

## 4.2 GIS Data Review

Prior to model development, review of the wastewater system GIS data was completed to identify any "data gaps" that needed to be rectified prior to development of the SewerGEMS model. Data gaps that were noted include the following items:

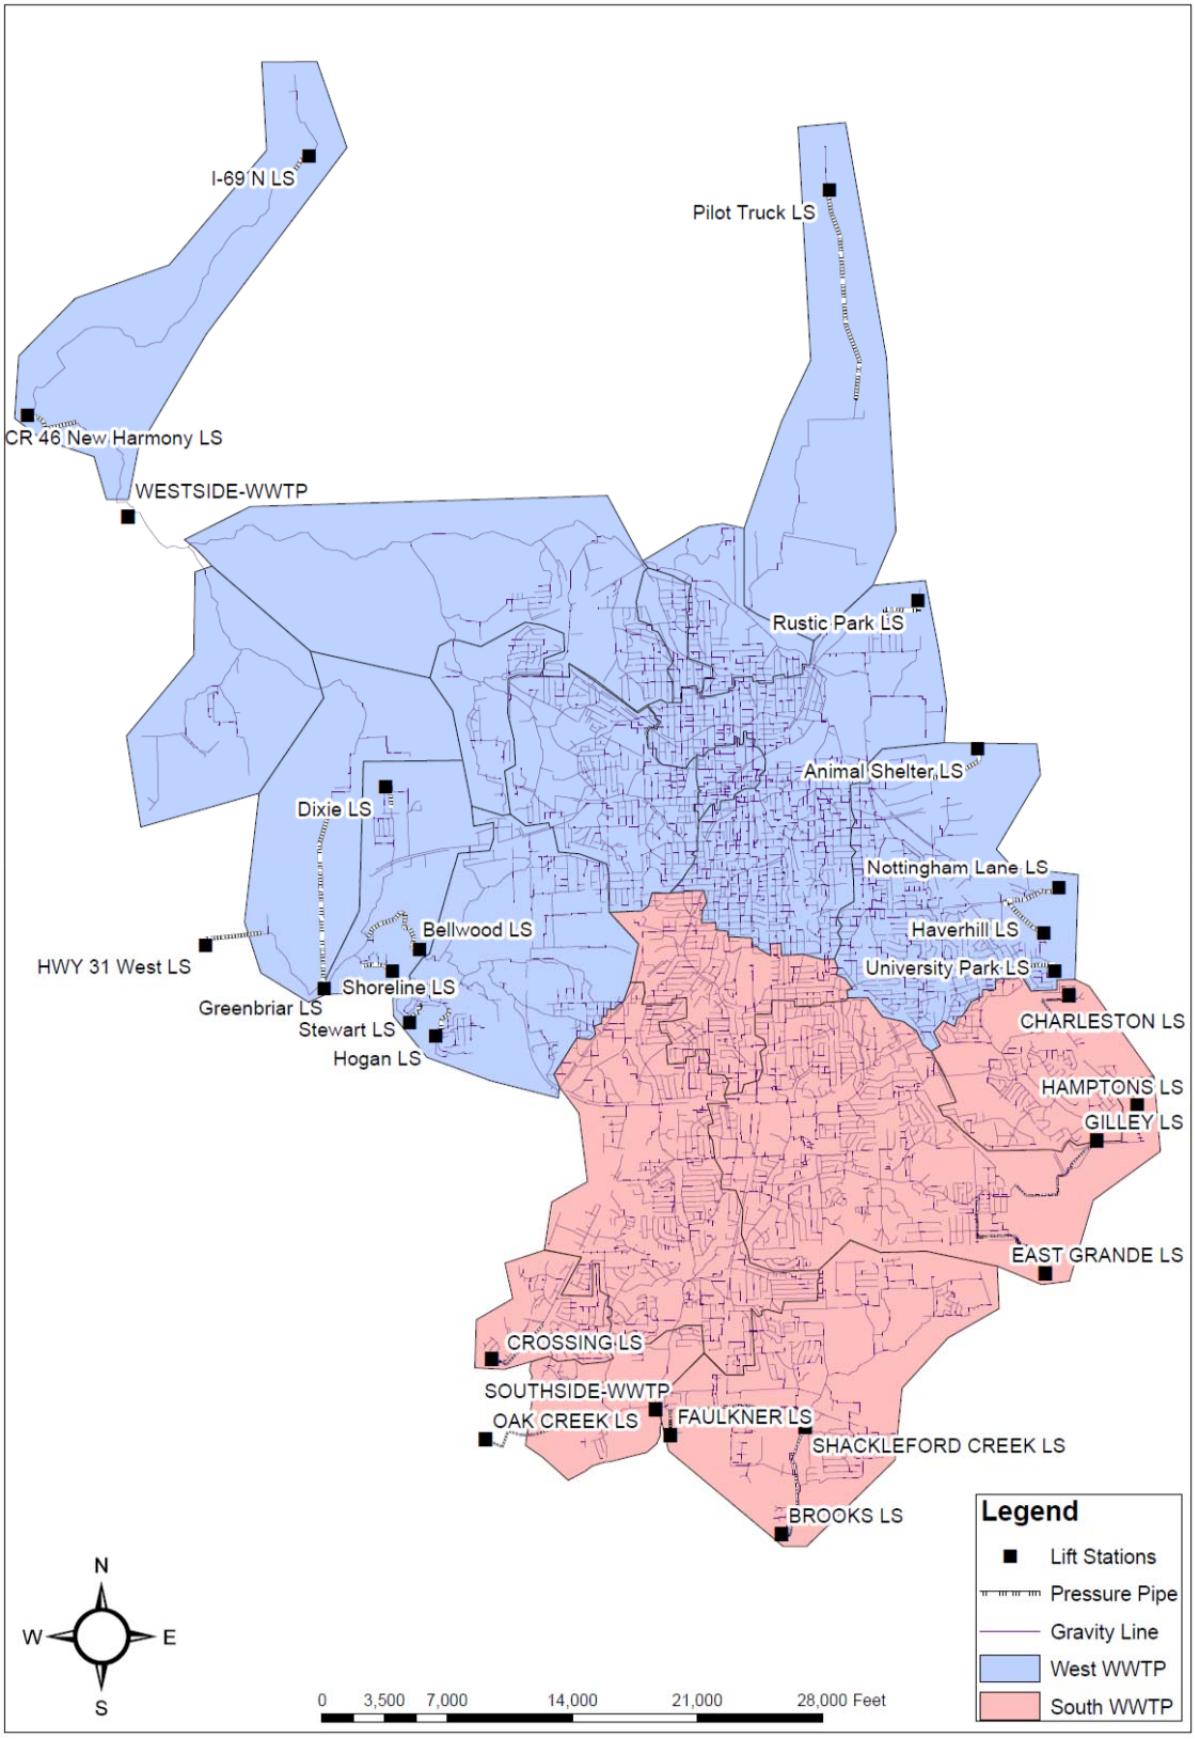
- 31% of the pipes were listed in GIS with unknown diameters and for these pipes the modeler obtained information by inferring from upstream and downstream pipes or assigned a 6-inch diameter if enough information is not available for inference. As asset condition data is collected the attribute data will be updated in GIS and the model.
- Manholes elevations and inverts on segments ten (10) inch and greater pipes that were not surveyed due to access issues or not being able to locate in the field were manually assigned using adjacent pipe depth, ground slope and connecting pipe slopes.
- Where data gaps occurred sequentially, making manual assignments of physical characteristics to the system difficult, TCEQ minimum slope requirements were assigned.
- Connectivity gaps included:
    - Manholes not connected to pipes
    - Pipes missing upstream/downstream manholes
    - Pipes/Manholes not having City assigned IDs
    - Manhole invert elevations above pipe inverts
    - Manhole invert elevations above ground elevation
    - Wet well not connected to influent pipes

As-built drawings were reviewed to collect missing information on pipes, force mains, lifts stations and recently constructed infrastructure not yet in the GIS database. Connectivity gaps were reviewed using connectivity tools in SewerGEMS to also ensure all pipes, manholes and wet wells are all connected. Once all the data gaps were resolved, the sanitary network attributes were imported into SewerGEMS. Data imported into the model included pipe ID, manhole ID, pipe diameter, invert, length, material type, and rim elevation.

## 4.3 Physical System Geometry/Model Network

A model network is a reflection of the physical features and geometry of a wastewater collection system. As shown in Figure 2, there are two individual collection systems for the City of Tyler, each with its own wastewater treatment facility. The two service basins are the Westside WWTP basin and the Southside WWTP basin. A separate model was created for each service basin, and each basin was subdivided into sub-basins based on the location of the flow meters. Modeled sewer pipes are presented in Appendix E.

**Figure 2 - City of Tyler Wastewater Service Areas**



The model created for each basin represents an all-pipe system consisting of all lines known to be in the system. While every pipe is accounted for in the model, only manholes with pipes of diameter 10-inch and greater were physically surveyed and inspected in the field. The survey data was then combined with GIS data for small diameter pipes to accurately build the model infrastructure and connectivity. Existing GIS data for manholes and pipes was modified to best fit the survey data when discrepancies were found. Table 2 shows the total length of wastewater lines and force mains input into the model based on existing GIS data and as-built drawings. Additionally, a breakdown by pipe material for the entire system can be seen in Tables 3.

**Table 2 - City of Tyler Wastewater Collection System Pipe Inventory**

There are twenty (20) lift stations that are owned by the City of Tyler and three (3) private lift stations. Lift station parameters were acquired from City record drawings as well as actual field measurements and observations, and pump suppliers. This information is presented in Appendix B. All lift stations and corresponding parameters were manually entered into the model to accurately portray the existing system.

## 4.4 Wastewater Flows Generation

Wastewater flows can be estimated and distributed throughout a model using several methods. However, when flow data is available, the most accurate and appropriate method is the wastewater-to-water conversion method. The wastewater-to-water conversion method utilizes water consumption data, based on utility billing records, to estimate wastewater flow rates for individual residences, commercial establishments, and industries. In most collection systems and under normal conditions, wastewater flows are proportional to water demands. A large portion (typically around 50-70%) of residential and commercial water consumption is returned to the wastewater system after being used. The wastewater flows can be calculated by applying a factor (termed the wastewater-to-water factor) to the water consumption data such that the average flow at each flow meter is a percentage of the average consumption of all customers in the sub-basin. Additionally, since the water demands are known for each customer and can be spatially assigned to the model, they can be accurately aggregated to the nearest node or manhole in the model network. A higher than typical wastewater-to-water factor could be

indicative of large point source inflows, substantial infiltration caused by damaged or significantly degraded wastewater lines, and undocumented sewer connections.

### 4.4.1 Flow Metering Sub-Basins

A flow metering sub-basin is composed of all the tributary collection system upstream of a flow meter site. The flow metering device used by Pipeline Analysis LLC was the Telog RU-33 data logger with Hach FL900 area/velocity sensor. The metering was conducted from April 15, 2015 through June 15, 2015 for all meters and December 15, 2016 through March 15, 2017 (meter sites 002, 003 and 018 only). Only the yearly water consumption per flow metering basin for 2015 was used in the development of the wastewater-to-water factors to ensure that the two data sets had the most similar metering periods.

As a form of flow metering data quality control, Table 4 is presented to compare the average WWTP flow to the average flow of the most downstream metering data during the same dry weather time period. Since the unmetered area represents a small portion of the entire system, its effect in the data comparison is considered insignificant. The averages of the WWTP flow and that of the metering data for the system are nearly identical during the dry weather monitoring period.

**Table 4 - WWTP Effluent Flow Summary**

| | Dry Weather Period | | Percent |
|---|---|---|---|
| Service Area | WWTP Effluent | Flow Meter Flow | Meter to WWTP |
| South | 6.913 | 6.88 | 99.5% |
| West | 10.904 | 10.87 | 99.7% |
| Total | 17.817 | 17.75 | 99.6% |

### 4.4.2 Water Consumption

Water consumption data was provided by City of Tyler through the utility billing records from October 10, 2013 to March 7, 2016 in excel and converted to geographic information system (GIS) shapefile format based on unique location identifiers. The shapefile database contained various information that was used to allocate the flows to the correct geographic location (i.e., manhole) within the collection system. This included information such as jurisdiction, class, customer names, addresses, location/customer ID and monthly water consumption for each customer over the two-and-a-half-year period. The 2014 and 2015 utility billing records showed city-wide consumption totals of 18.0 and 18.5 MGD respectively.

When using water consumption data to estimate wastewater flows, special attention must be given to the largest water users, or Large Volume Users (LVUs). Many of the LVUs are industrial customers who treat and reuse a majority of the water or consume a majority of water through industrial processes in lieu of discharging it back to the City's wastewater system, they do not typically follow the same discharge pattern of the rest of the customers in the sub-basin and must be considered on a case-by-case basis. It is typical to temporarily remove LVU's consumption and discharge data from its encompassing sub-basin as to not affect the wastewater-to-water factor. In order to accurately define the flow contribution and patterns of a LVU from that of the encompassing sub-basin, regular water consumption and wastewater discharge readings prove to be very beneficial when available. Wastewater loading data for individual LVUs was not available for this model. As a result, the LVUs were grouped with and assigned diurnal patterns and wastewater-to-water factors identical to the other customers within each sub-basin. Dividing the two basins into 20 metered sub-basins proved especially helpful for ensuring that individual LVUs did not negatively influence the calibration effort.

Situated in the West WWTP service area are 148 residential sewer-only customers. These customers do not purchase water from City of Tyler and as a result, their annual average consumption is unknown. For each of those customers, it was assumed that their contributing wastewater loads were equal to the city wide customer average water consumption.

### 4.4.3 Dry Weather Flows

Dry weather flows (DWF) are those that occur in the wastewater system during dry weather periods where the system is under no influence of rainfall dependent infiltration and inflow (RDII). DWFs are the actual wastewater flows intended to be conveyed in a wastewater system, without the addition of storm water or surface water flows.

The flow meter data provided by Pipeline Analysis LLC was used to calculate the DWFs. The DWFs (loads) for each individual customer were calculated based on the water consumption data provided by the City and the associated dry weather wastewater-to-water factor calculated for each sub-basin. The average annual water consumption for each customer was multiplied by the sub-basin specific wastewater-to-water factor.

The resulting daily average wastewater flows for each customer were then spatially distributed to all customer locations using Bentley's LoadBuilder Wizard. The allocated flows are considered the base flows in the model. The nearest pipe-nearest manhole method was used for assigning the factored flows to the model. This loading method assigns customer flows to the closest pipe, and then distributes these flows to the nearest manhole on the closest pipe.

## 4.5 Diurnal Curves

Knowledge of accurate flow variations over a 24-hour period is essential for proper extended period simulation (EPS) modeling analyses of a wastewater system. Daily wastewater flow variations within a sub-basin are heavily influenced by the customer's water use and demand patterns. Typically, for sub-basins made up of primary residential customers, the peak flows occur in the morning hours between 6:00 am and 10:00 am, when customers wake to begin their daily routine and between 6:00 pm and 10:00 pm, when customers return home and begin their nightly routine.

A diurnal curve represents the wastewater flow variations at a particular point in the system over a 24-hour period. In this modeling effort, the diurnal curves were developed in 15 minute time increments, and were developed for each sub-basin to match the flow metering data.

Quarterly-hour flow patterns were represented by the development of a diurnal curve for each flow metering basin. During an unsteady extended period, simulation (EPS), the diurnal curves are applied to the base flows at each time step.

The diurnal curves were later refined during the calibration period. Typical diurnal curves for each service area can be found in Appendix A.

## 4.6 Modeling Limitations

### 4.6.1 Software

The SewerGEMS software is equipped with two stand-alone programs, SewerGEMS/CivilStorm and SewerGEMS/SewerCAD. Each program performs the hydraulic calculation using a different "engine" or mathematical solver, so it is necessary for the modeler to determine which version of the software is a

best fit for the collection system being modeled. The SewerGEMS/CivilStorm program should be used when needing to quantify overflow volumes, to perform catchment rainfall-runoff calculations or when dynamic wave solutions are desired. The SewerGEMS/SewerCAD program should be used for systems having complicated pumping arrangements, a high number of lift stations, pressure sewers or those desiring automated design. In general, Table 5 below indicates the standard features of each and summarizes when each should be used.

**Table 5 - Features in SewerGEMS/CivilStorm & SewerGEMS/SewerCAD**

| SewerGEMS/CivilStorm | SewerGEMS/SewerCAD |
|---|---|
| Catchment hydrology (rainfall-runoff) | Complex pumping or controls |
| Dynamic wave (implicit) and/or SWMM (explicit) solvers considered more accurate as they provide improved ability to account for system storage. | Convex/Gradually varied flow solver is more stable and capable of handling complex pumping/controls and multiple lift stations |
| Pond and gutter elements | Automated design |
| Flow splits based on hydraulics | Diversion links/Interconnections |
| Channels and Cross Sections | Numerous Pressure Sewers/lift stations |

The City's terrain dictates the use of a number of lift stations (23 in the collection system) with standard pumping arrangements and no interconnections. In addition, the decision was made early on that a separate model would be created for the South and West basins, which would reduce the number of lift stations in each model. With this in mind, the modeling team first selected the SewerGEMS/CivilStorm program for its ability to account for storage in the collection system and is generally considered more accurate because of this. However, the team found it to be significantly unstable and, in most cases, provided solutions with a high degree of error while taking longer hours to compute. The software manufacturer confirmed this was the result of the number of lift stations and interconnections in the system and recommended the use of the SewerGEMS/SewerCAD program. SewerGEMS/SewerCAD program was chosen as the preferred modeling program for its ability to reliably handle the pumps in the system and the convergence to accurate solutions faster.

## 4.7 Modeling Assumptions

### 4.7.1 Physical Characteristics of Model Network

Industry standard assumptions were made in determining the physical properties of pipes and manholes in the absence of field data and as-built drawings. Pipe diameters not identified in the GIS data nor shown on utility base maps were assumed to be equal to the upstream pipe. Invert elevations of un-surveyed manholes were estimated as follows:

- Rim elevations of manholes were extrapolated from the City's two-foot LIDAR data or four foot where two foot was not available
- The flow line of the furthest upstream manhole was identified for each pipe segment and assigned a 4 ft minimum cover from the rim elevation
- Connecting downstream inverts were estimated by assigning TCEQ minimum slope to the pipe based on pipe diameter while also ensuring that 4-ft of cover was maintained at all times

This process was carried out for all un-surveyed pipes until reaching and tying into a surveyed segment of pipe 10-inch or greater. The inverts for both the surveyed and un-surveyed line segments were then checked to confirm there were no conflicts. The process was repeated for remaining pipe segments until

all inverts for un-surveyed pipe segment were calculated. The pipe invert data was then imported into the model using the existing GIS shape files provided by the City.

The ability to accurately measure pipe roughness is difficult and, in most cases, impractical in the field due to the tremendous variability in debris and line conditions. In addition, it would require a thorough and substantial sample size before the data could be extrapolated to the rest of the system. Therefore, industry standard roughness coefficients were assigned to all pipes in accordance with Table 6. Pipes designated as force mains used the Hazen-Williams formula for frictional loss computations. The roughness values chosen were consistent with standard practices and were refined during the calibration process.

**Table 6 - Pipe Roughness: Summary of Manning Coefficients**

| Pipe Material | Manning n |
|---|---|
| Asbestos Cement | 0.011 |
| Cast Iron | 0.012 |
| Concrete | 0.013 |
| Ductile Iron | 0.012 |
| Polyvinyl Chloride | 0.01 |
| Vitrified Clay | 0.013 |

### 4.7.2 Calibration Data

All customers within a sub-basin discharge wastewater to the collection system at different durations, quantities, and times of the day and as a result, produce their own site specific diurnal flow pattern. Typically, this can even vary from day to day. An assumption was made for every wastewater customer within a flow metered sub-basin to have the same wastewater loading pattern. As a result, the diurnal curves developed for each sub-basin have been applied to all flow contributions within that sub-basin homogeneously.

Although RDII is dependent upon many parameters such as pipe condition, groundwater tables, and number/size of point source inflow connections, specific locations of uncharacteristic RDII were not identified. All pipes within a flow metered sub-basin were assumed to have the same RDII response parameters.

Some portions of the service basins were unmonitored for dry weather and wet weather data. These unmonitored areas of the service basins were assumed to have similar wastewater flow and pattern characteristics to the adjacent sub-basins being monitored.

## 4.8 Hydrologic Parameters

### 4.8.1 Dry Weather Event Selection

During dry weather, the pattern and flow of wastewater production is rather predictable with some possible differences between weekdays and weekends. For the City of Tyler, there was no distinction between weekday and weekend dry weather patterns identified. In sub-basins where dry weather flow patterns seem to have a non-typical residential sanitary sewer loading pattern, less stringent criteria for defining dry weather days was applied to the data set in order to get a larger sample size and confirm the pattern shape.

### 4.8.2 Wet Weather Events Selection

The rainfall data used for wet weather flow is of critical importance for wastewater models and for evaluating the performance of a collection system. The storms selected should cover a variety of hydrologic events, but, in general, use of several large events will improve the model's accuracy since it will be used to predict the response to the design storm. However, if a storm with similar characteristics to the design storm exists in the data set, then it is preferred to use the properties of said storm along with compiling the average characteristics of multiple storms. During May 11, 2015 a 2.77 inch to 5.71 inch six hour storm was recorded with its area of peak intensity situated over flow metering basin 15 which is located near the geographic center of Tyler. The 5-year 24-hour design storm has a depth of 5.78 inches. The May 11, 2015 storm has similar characteristics as the design storm and as a result, a majority of the calibration efforts focused on this rain event.

# 5.0 Model Calibration

Model calibration is a repetitive process consisting of the adjustment of modeling parameters within reasonable limits to obtain simulated results that recreate the actual behavior of the wastewater collection system. The process of adjusting both hydrologic and hydraulic variables to best match actual measured dry and wet weather flow data was adopted in this model.

## 5.1 Calibration Goals and Tolerances

The parameters used in dry weather calibration were +/- 10% of recorded values for peak flow rate and flow volume. During wet weather, the parameters were increased to -15% to +25% of recorded value for peak flow rate and -10% to +20% of recorded flow volume. These parameters were applied to every flow metering point within the model. Replicating shape and timing was a goal for both dry and wet weather calibration. Replicating shape and timing entailed having similar amounts of peaks and troughs and having them occur at similar times within +/-1 hour of a recorded times.

## 5.2 Model Calibration Methodology

The calibration methodology included two distinct elements:

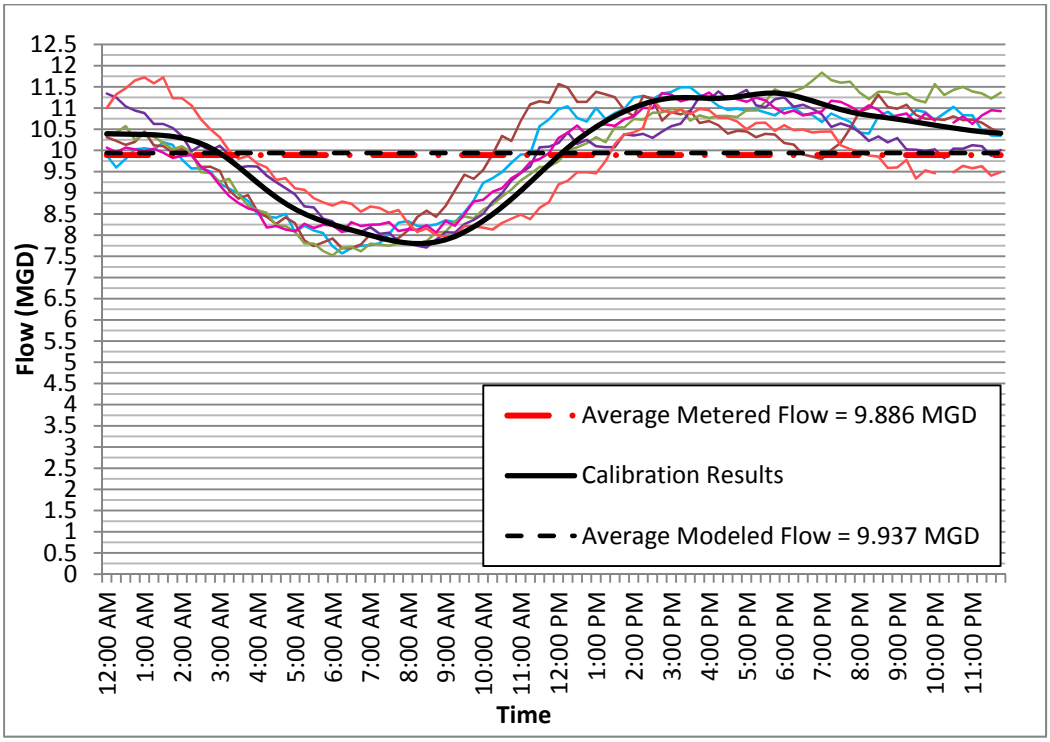
1. Dry weather calibration
2. Wet weather calibration

Each of the steps requires different types of flow metering data for the selected dry and wet weather events.

## 5.3 Dry Weather Calibration Process

The dry weather calibration process involved comparing observed data to model results for dry weather periods to ensure the dry weather flow is accurately simulated. The wastewater-to-water factors and the diurnal curves for each monitored sub-basin were refined individually until the model predicted flows (volumes, peaks and patterns) were in agreement with the flow meters. The wastewater-to-water factors were adjusted such that the wastewater loads matched the total average flow volume at the flow meter. The diurnal curves were refined so that the 24-hour flow variations were properly replicated. An iterative process of identifying and investigating issues, adjusting parameters, factors and rerunning the model were conducted until the simulated results matched the metering data. Figure 3 illustrates an example of the dry weather calibration modeling results for FM 003. The results of the dry weather calibration for each metered sub-basin are included in Appendix C.

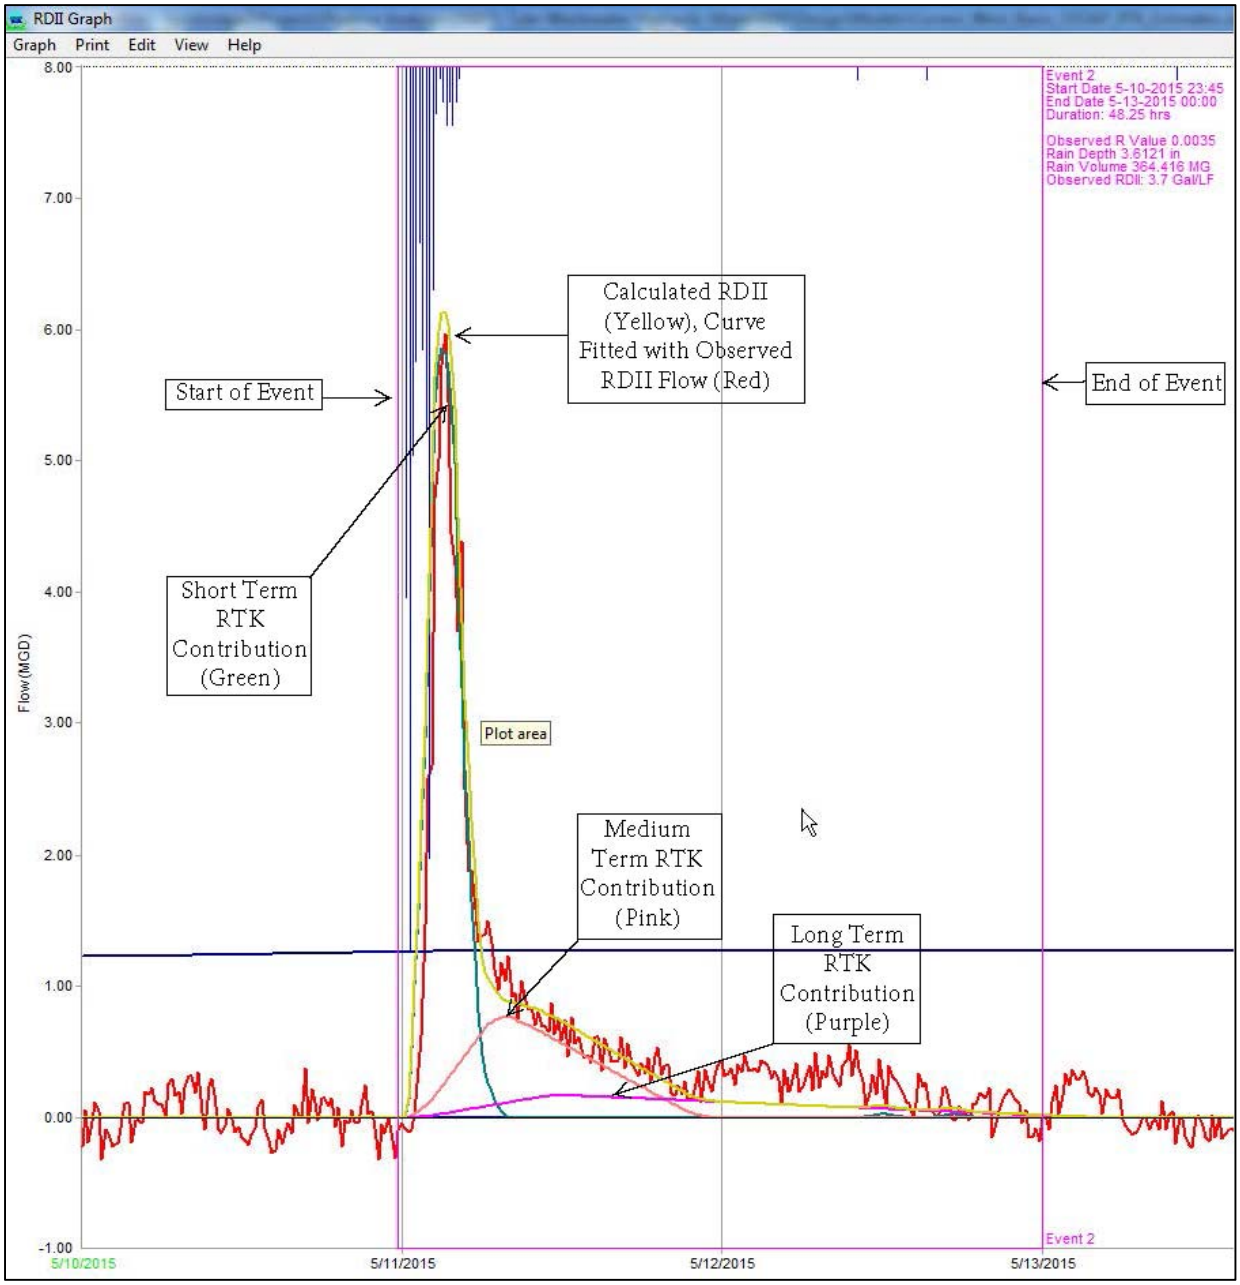
**Figure 3 - Example of Dry Weather Calibration Results**



## 5.4 Wet Weather Calibration Process

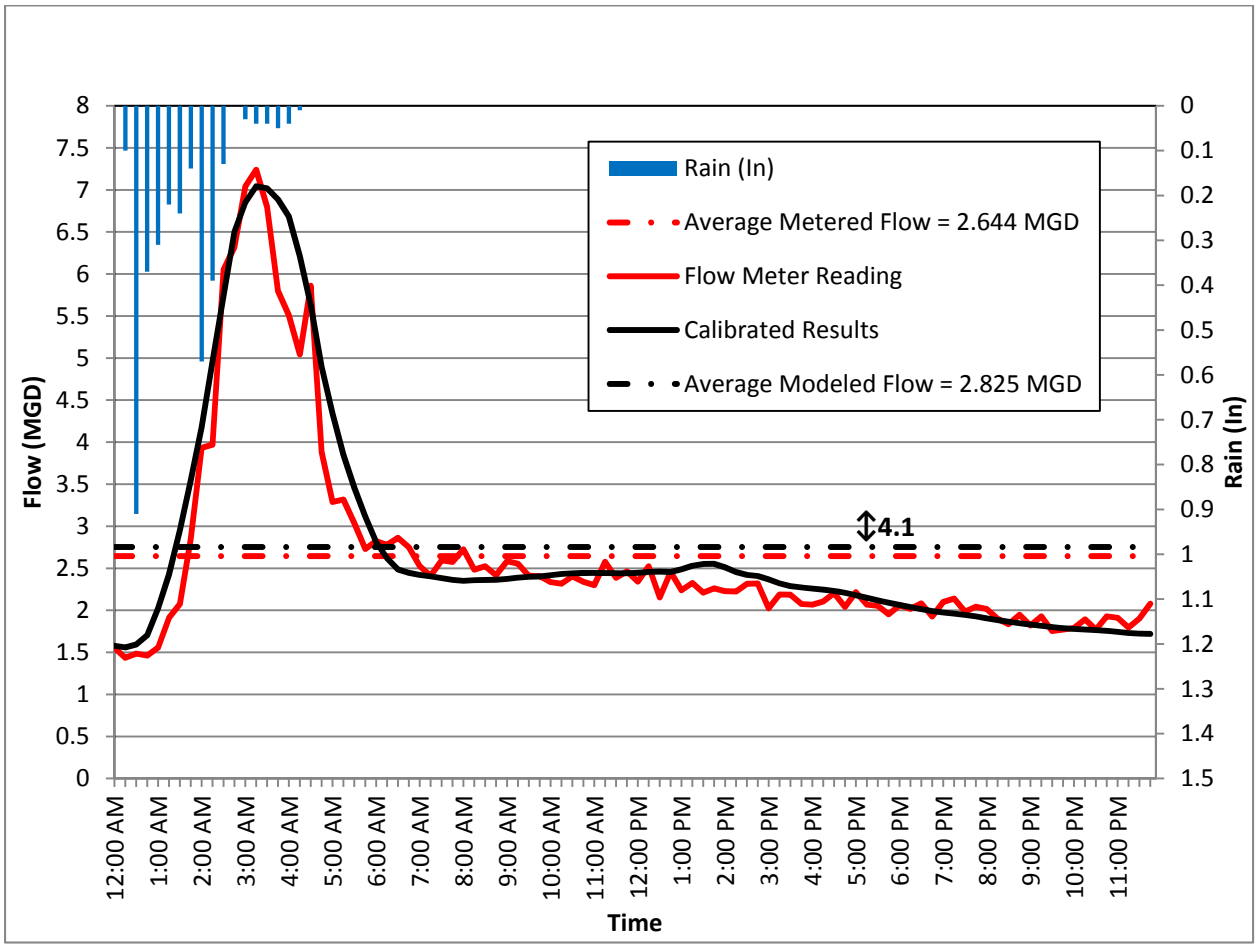
The wet weather calibration process consisted of first, calculating the RTK values for each of the sub-basins with their corresponding selected wet weather events. This was accomplished by exporting the rainfall data and flow meter data for each sub-basin in to SSOAP. SSOAP creates a hydrograph by using the modeler provided RTK values and then overlays that result on the metered flow data. By adjusting the RTK's until the SSOAP generated hydrograph matched the metered flow data, RTK's were obtained that could then be exported into SewerGEMS. Figure 4 demonstrates the SSOAP RTK generation process. If needed, the SSOAP obtained RTK values were then adjusted within the SewerGEMS model to again replicate the metered flow data within the parameters discussed in Section 5.1.

**Figure 4 - Example of SSOAP Generated RTK Graphs**



SewerGEMS can only allocate the RDII flows obtained from RTK's to a single pipe segment or manhole. To more accurately distribute the RDII flows upstream of a metering point, first the RDII volume of the storm event is calculated by subtracting the dry weather hydrograph from the SewerGEMS RTK wet weather generated hydrograph. The RDII volume is then turned into an average RDII flow by dividing it by the time the storm is seen to have an I/I effect on the system. The RDII flow is then divided by the total length of wastewater lines in its corresponding sub-basin to determine RDII flow per-linear foot. This value is then multiplied by each pipe segment's length in the sub-basin. If needed the unit hydrograph obtained by subtracting the dry weather hydrograph from the SewerGEMS RTK generated hydrograph is adjusted to again replicate the metered flow data within the parameters discussed in Section 5.1. Figure 5 shows the final model generated wet weather flows overlay upon to its corresponding metered flow.

**Figure 5 - Example of Wet Weather Calibration Results - Meter 014**



The final hydrographs and wet weather calibration results were recorded for each metered sub-basin and can be found in Appendix D.

## 5.5 Sensitivity Analysis

Performing a sensitivity analysis is critical to gaining confidence in the modeling results and in achieving a well calibrated model. It helps the modeler gain a better understanding and certainty of which of the various modeling inputs have the greatest and least impact on these results. Performing a sensitivity analysis on a hydraulic model consists of modifying different parameters within reasonable limits and evaluating the level of impact these parameters may have on the modeling output. The parameters fall into many categories such as flow data (patterns, water demands, load location), pipe data (roughness, slope, diameter), manholes (flow lines), and pumps (controls, wet well levels, pump curves).

The sensitivity of the model is tested by modifying a single type of parameter at a time and repetitively running the model to determine how sensitive the output is to the input. This process was completed during the dry weather and wet weather calibrations and ultimately served as a guide to achieving a well calibrated system.

# 6.0 Design Wet Weather Event

The 5-year, 24-hour assessment storm was selected as the most appropriate storm for the City of Tyler model evaluation and is in compliance with the Consent Decree.

## 6.1 Design Rainfall Event Selection

While recognizing the need for one, the US Environmental Protection Agency (EPA) does not currently have a standard for design rainfall events when trying to determine the limits of the sewer system to convey flows without incurring SSO's. It does not, however, allow any wastewater overflows under any conditions.

As mentioned above, the design rainfall event selected for this study was an event having a 5-year return period and a 24-hour duration. This designation is somewhat meaningless without a specific volume or, more importantly, a defined distribution. The RTK method was used to define the design storm event. The selected methodology is discussed in the next section.

## 6.2 Design Rainfall Volume and Distribution Methodology

As mentioned above, the RTK method was used to distribute RDII throughout the system. This method breaks the wet weather hydrograph into three separate triangular hydrographs, which can be described by three parameters R, T and K. R is the fraction of precipitation that shows up as runoff, T is the time to peak of the hydrograph and K is the ratio of the recession time to the time to peak. The R values depend on the problems with the sewers (i.e. leaks, illegal connections, missing lateral cleanout caps, etc.) In theory, R should be zero in a perfect sanitary sewer system. The sum of all the R's should be significantly less than one (1) because some water flows to storm systems, some seeps into the ground and some is lost to depression storage and evapotranspiration. The R's are usually around 0.1 but depend heavily on the condition of the system. The T values depend on the size of the catchment with the rapid inflow T much smaller than the long-term infiltration T. K depends on the relative length of the recession curve but it usually on the order of 1.5 to 3, with 1.67 being a typical value used in SCS triangular curves.

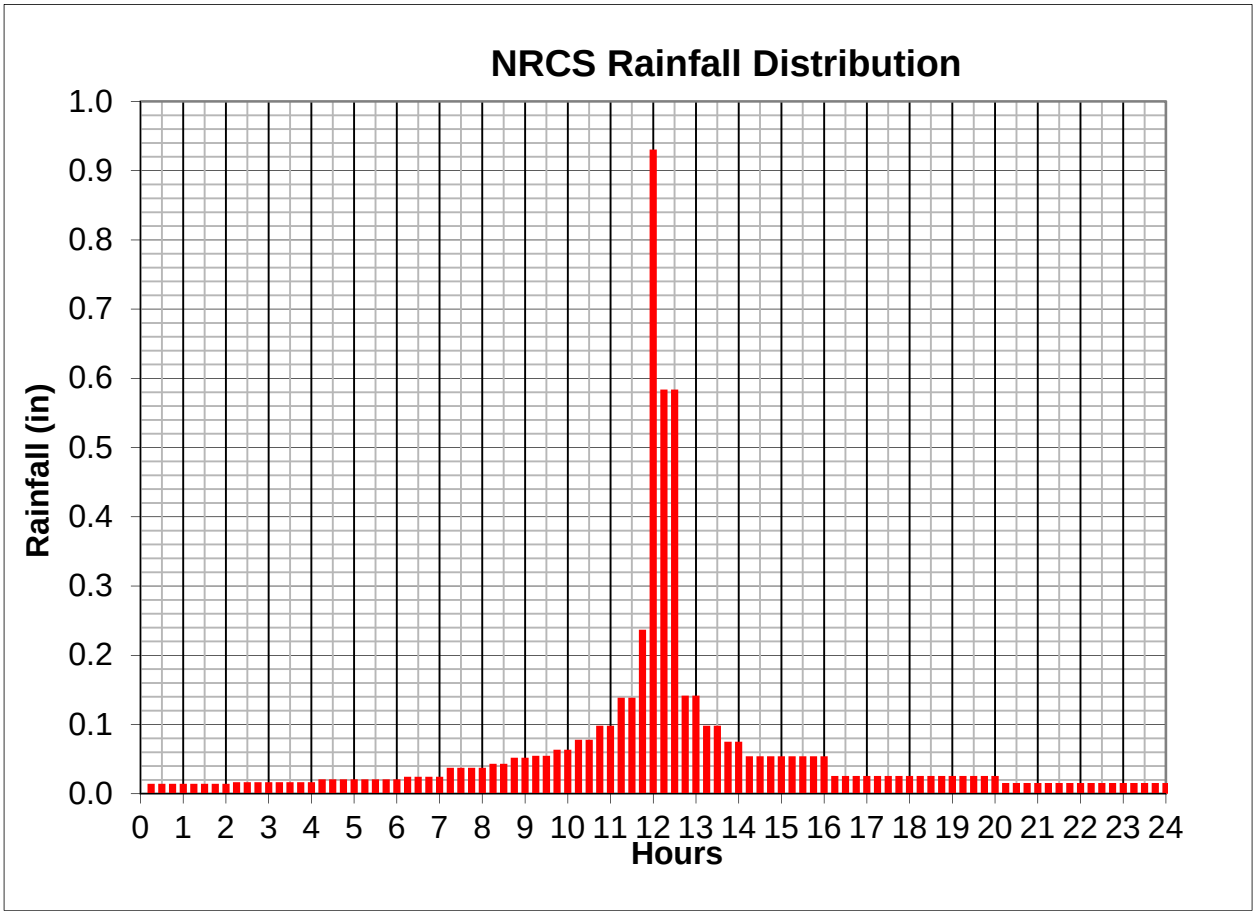
There are two approaches to apply the RTK method. The first method applies RTK values for an entire storm based on the total precipitation; however, this approach is only applicable for storms with similar

precipitation durations and patterns. A second method applies RTK parameters as a unit hydrograph and can be applied to different rain events.

Due to the fact that the recorded storm during the flow metering period was similar in precipitation and the pattern to the 5-year-24-hour event, the first method was used in applying the RTK parameters.

Peak wet weather flows were determined based on the 5-year-24-hour rain event. According to the US Department of Commerce May 1961 Technical Paper No. 40, the amount of precipitation expected in the City of Tyler over a 24-hour period for the 5-year storm is approximately 5.78 inches. Figure 6 shows the 5-year-24-hour design storm hyetograph used for the modeling analyses.

**Figure 6 - 5Yr 24Hr Design Storm Hyetograph**



## 7.0 Next Phase of Model Work Tasks

With the development of this city-wide hydraulic model, the analysis of system capacity can be undertaken in accordance with the requirements of the consent decree. The next modeling tasks will include identifying Potential Capacity Constraints (PCCs), performing field verification to establish Confirmed Capacity Constraints (CCCs), perform alternatives analysis and prepare both the Capacity Assessment Report and Capacity Remedial Measures Plan prior to October 2020.

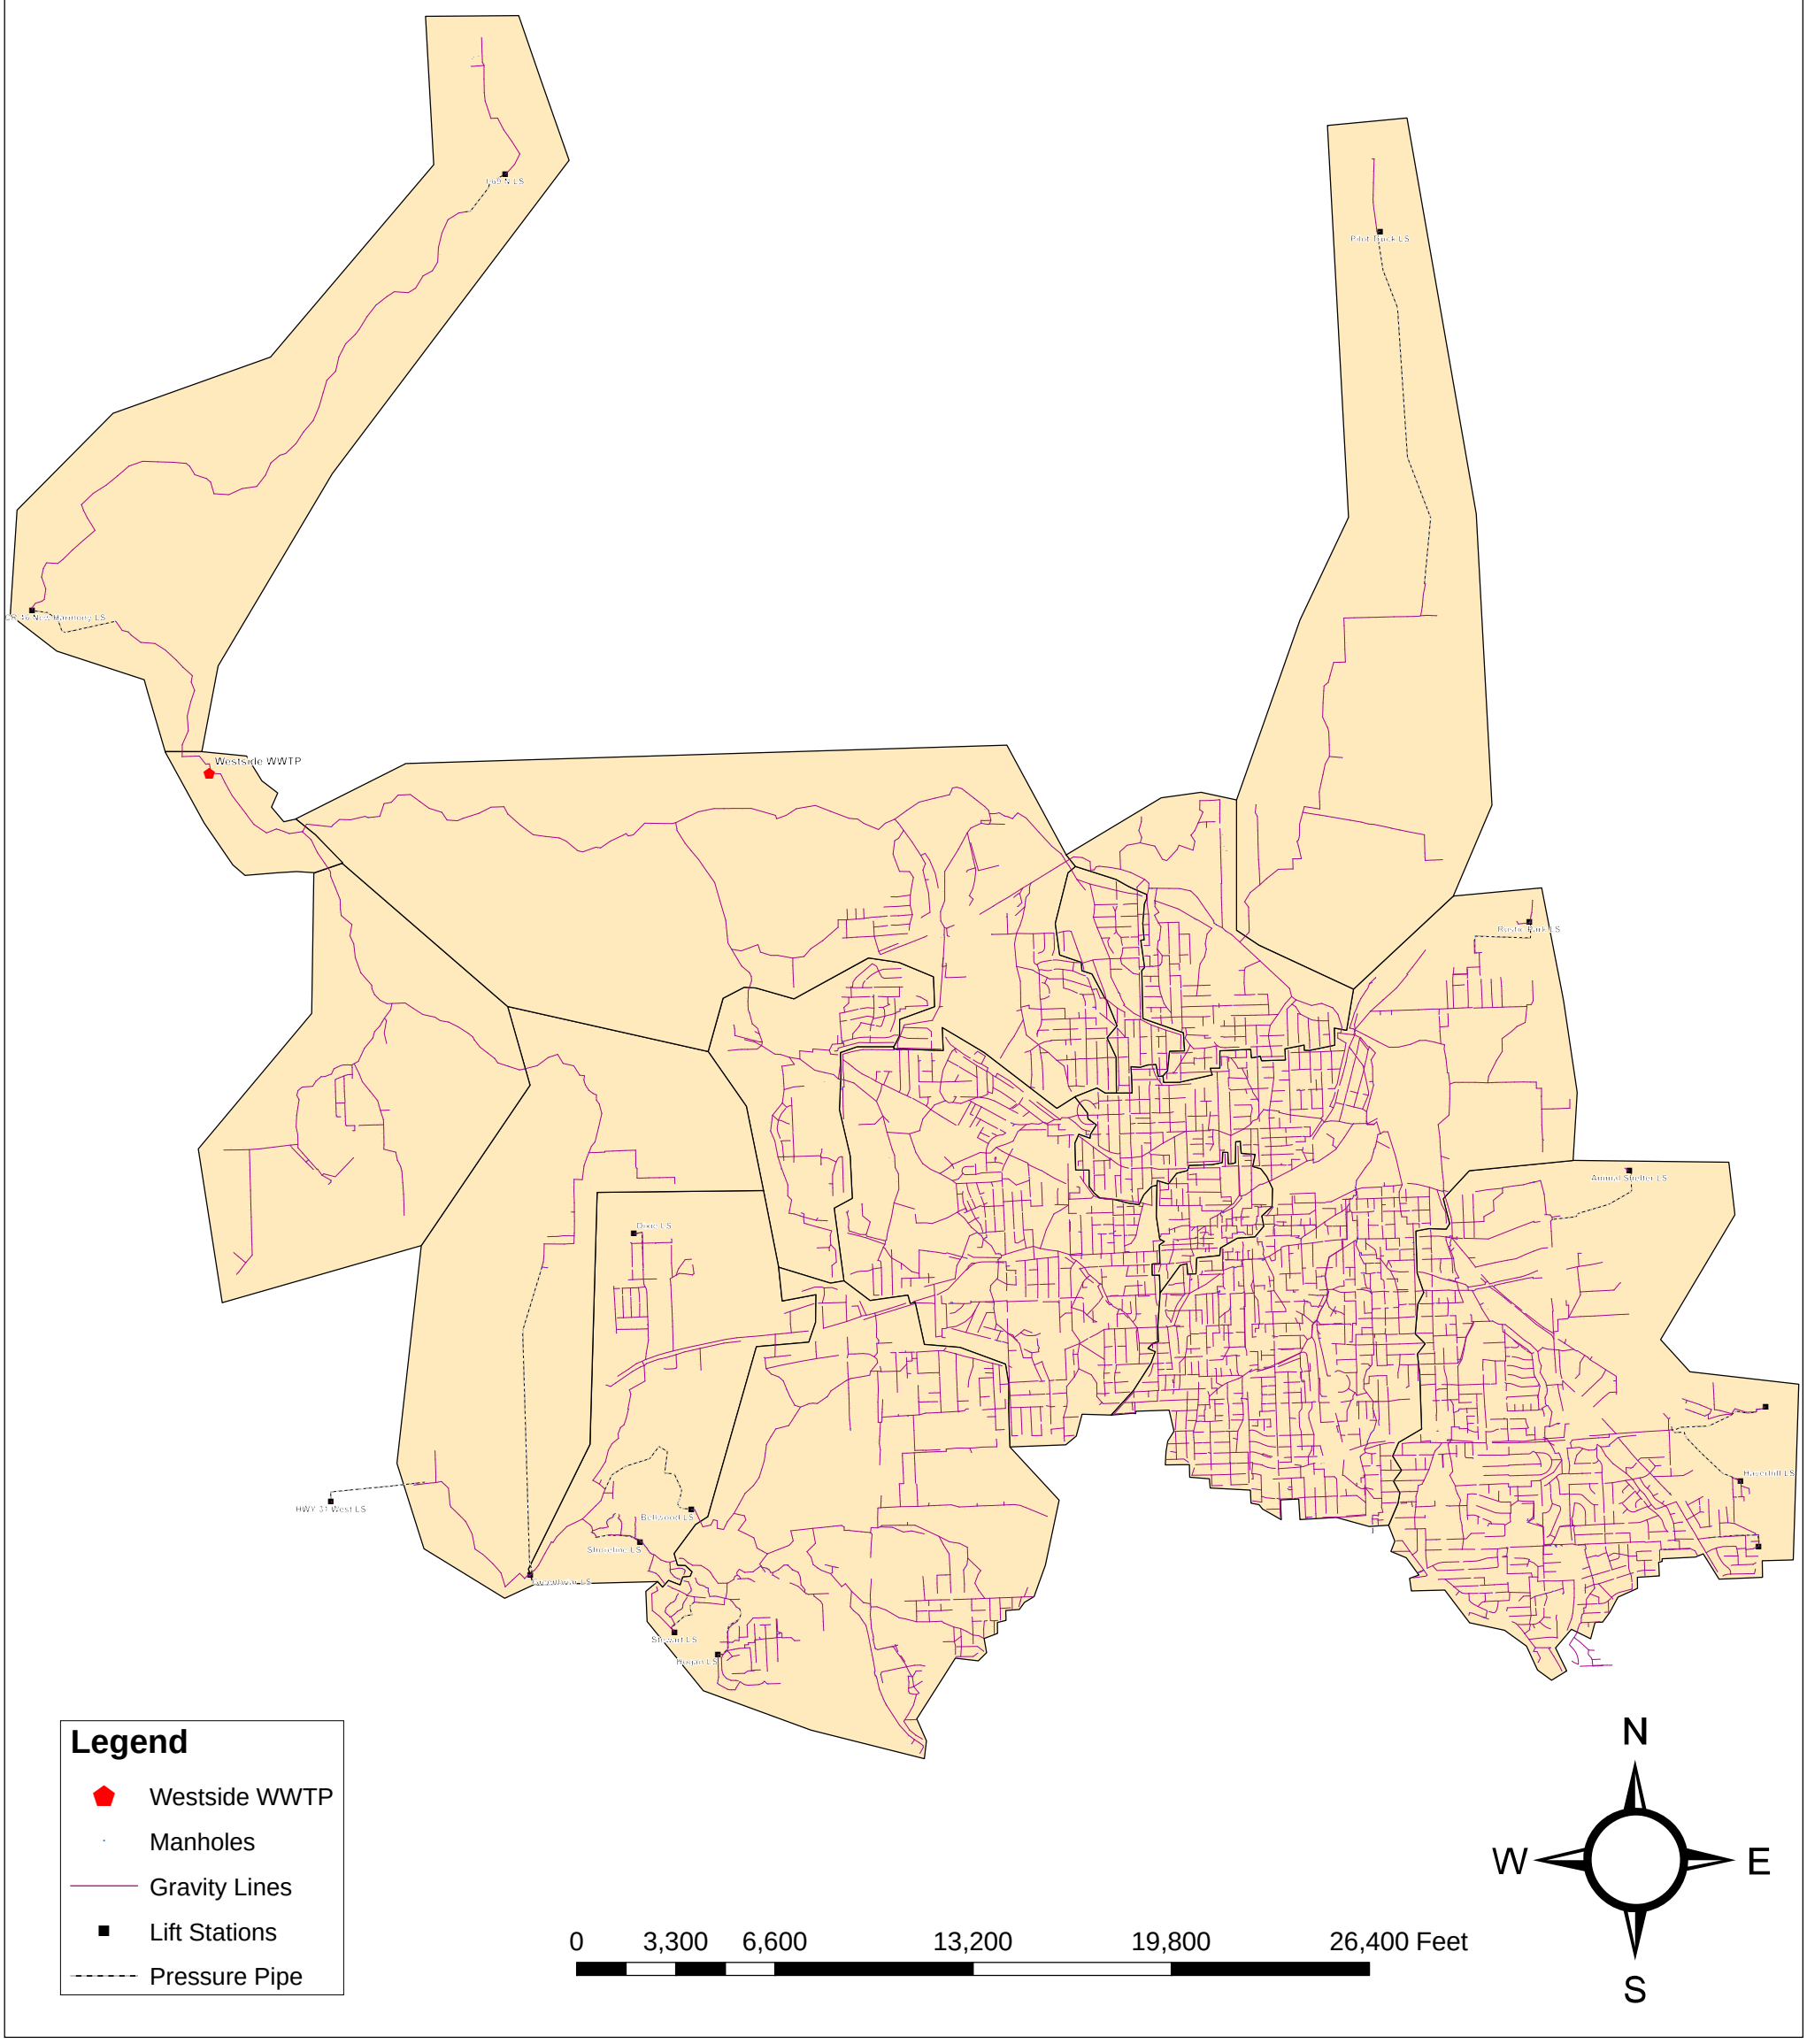
# Appendix E



# WEST BASIN

Notes;
1. This exhibit illustrates the locations of gravity lines, pressure pipe, manholes, and lift stations included in the SewerGEMS model. The Sub-Basin boundaries are also depicted.
2. The gravity lines are labeled by model ID.

# SOUTH BASIN

Notes;
1. This exhibit illustrates the locations of gravity lines, pressure pipe, manholes, and lift stations included in the SewerGEMS model. The Sub-Basin boundaries are also depicted.
2. The gravity lines are labeled by model ID.
